Affected version:	
Description:	A feature which is present in redmine/chiliproject, is the ability to authorize users to create projects. This is done by setting this permission to the roles we want. Now, here is a (I think) common case where it is a problematic choice : In my company we use redmine (one day, chili will take its place I hope) for our forge. All collaborators have access to this forge but our clients too. Collaborators connect using LDAP and clients using internal auth. Any collaborator must be able to create a new project so we allow Non Members to do it. But ! It means that our clients can create projects too... We wrote a small plugin to filter the permission based on the auth_source but I think it would be preferable to rethink the subject to make more logical. Needing to already be member of something to create project is, to me, a non sens. What do you think guys ? :)

- Status changed from Open to Duplicate

This issue could be solved with the introduction of global rights and roles (as proposed in #121)

Currently the "create project" right is really a bad hack. You gain this permission, by being member of any project with a role that has this permission. This should be changed to having real global permissions and being able to assign it to users and/or groups.
